Received 3 May 2007/Returned for modification 25 June 2007/Accepted 3 August 2007

We report a case of *Aspergillus tamarii* keratitis. Ocular injury was known to be a predisposing factor. Topical natamycin and econazole treatment and subsequent systemic ketoconazole treatment proved effective. The isolate was identified by morphological characteristics and sequence analysis as *A. tamarii*, a member of *Aspergillus* section *Flavi* not hitherto reported from keratomycosis.

**CASE REPORT**

A 32-year-old female from Coimbatore was presented to the Aravind Eye Hospital, Coimbatore, South India, on December 27, 2005, with complaints of pain, redness, and defective vision of a 4-day duration in the left eye. She indicated that she had suffered an ocular injury caused by an iron piece while hammering 4 days earlier. On examination, her uncorrected visual acuities in the right and left eyes were 6/9 (partial) and 1/2/60, respectively. An anterior segment examination of the left eye showed edema of the lid and conjunctival congestion. The cornea showed lid edema and conjunctival congestion. The cornea suffered an ocular injury caused by an iron piece while hammering 4 days earlier. On examination, her uncorrected visual acuity having improved to 6/18. The patient showed improvement during the next 3 weeks; the infiltrate reduced gradually, and the anterior segment inflamations subsided. On the last review, the anterior segment of the left eye showed a central nebular scar, with the best corrected visual acuity having improved to 6/12. The patient was advised to use glasses and to report for review after 6 months.

The clinical isolate was further examined at the CBS Fungal Biodiversity Centre and at the University of Szeged for species assignment and antifungal susceptibility tests.

**Myological study and diagnosis.** The fungus was subcultured on malt extract agar plates and identified as *Aspergillus tamarii* Kita based on the colony morphology and microscopic features of the isolate (Fig. 1 and 2). Colonies on malt extract agar at room temperature attained diameters of 6.0 to 7.0 cm in 10 days, producing abundant conidial heads in dull yellowish green shades becoming metallic bronze at maturity (24). The conidiophore stipe was hyaline and rough walled; the conidial heads were radiate; the vesicles were globose to subglobose, 25 to 50 μm in diameter. The phialides were borne directly on the vesicle or on metulae (mostly on large heads). The conidia were globose to subglobose, 5 to 6.5 μm in diameter, and brownish yellow. However, in contrast with those of typical wild *A. tamarii* isolates (Fig. 2A), some conidia of this isolate were not ornamented with tubercules and warts but were smooth walled and hyaline (Fig. 2B). The isolate grew well at 37°C but was unable to grow at 42°C on malt extract agar medium.

For purposes of molecular identification, mycelia grown in liquid YPG medium (0.5% Bacto yeast extract, 0.5% Bacto peptone, 1% glucose) for 1 day were subjected to DNA isolation by a Masterpure yeast DNA purification kit (Epicenter Biotechnologies, Madison, WI) according to the manufacturer’s instructions. The internal transcribed spacer (ITS) region of the rRNA gene complex, incorporating ITS 1, the 5.8S rRNA gene, and ITS 2, was amplified using primers ITS1 and ITS4 (26). A segment of the calmodulin gene was amplified using primers cmd5 and cmd6 as described by Hong et al. (12), while a segment of the β-tubulin gene was amplified using primers bT2a and bT2b (9). DNA sequences were determined using a BigDye Terminator v3.1 cycle sequencing kit.

(Applied Biosystems Inc., Foster City, CA) and an ABI 3100 DNA sequencer. Both strands of each fragment were sequenced. The resulting sequences were deposited in the GenBank database. Sequence analysis was carried out by a BLASTN similarity search (2) at the website of the National Center for Biotechnology Information (http://www.ncbi.nlm.nih.gov/blast/).

Table 1 lists A. tamarii sequences with complete homology to those of the case isolate. The ITS, tubulin, and calmodulin sequences of the case isolate proved to be completely identical to the corresponding sequences of A. tamarii strain NRRL 25565 (13).

Living cultures were deposited at the Department of Microbiology, Aravind Eye Hospital and Postgraduate Institute of Ophthalmology, Coimbatore, India (strain number 2342/05), and at the Centraalbureau voor Schimmelcultures (CBS 121598).

**Antifungal susceptibility testing.** The Etest method (AB BIODISK, Solna, Sweden) for molds was applied for the determination of MICs of amphotericin B, fluconazole, itracona-

Discussion. Corneal infections of fungal etiology are very common and represent 30% to 40% of all cases of culture-positive infectious keratitis. Combating fungal keratitis is of special importance in India, which harbors the largest agrarian population at risk for developing blindness due to the limited availability of antifungal drugs and the lack of response during therapy. Certain Aspergillus species, mainly Aspergillus flavus (23, 25), Aspergillus terreus (25), Aspergillus fumigatus (23, 25), and Aspergillus niger (4), have long been regarded as important pathogens in eye infections, especially keratitis. Other members of the genus less frequently occurring in keratitis include Aspergillus glaucus and Aspergillus ochraceus. Most of the Aspergillus strains isolated from keratomycosis patients are being identified and reported at the genus level only (10). Their molecular identification at the species level would be of great importance, as the pathogenic potential may vary between different species of the genus.

A. tamaari is a member of Aspergillus section Flavi (8). This species is widely used in the food industry for the production of soy sauce (known as red Awamori koji) (14) and in the fermentation industry for the production of various enzymes, including amylases, proteases, and xylanolytic enzymes (3, 7, 17). Although A. tamaari is able to produce several toxic secondary metabolites, including cyclopiazonic acid and fumigaclavines (24), it has rarely been encountered as a human pathogen. The only known cases are an eyelid infection (5), invasive nasosinusal aspergillosis in an immunocompetent patient (20), and onychomycosis in a 3-year-old boy (15). To our knowledge, the present case of fungal keratitis is the first report on an ocular infection caused by A. tamaari and the fourth known case worldwide involving this unusual opportunistic human pathogen.

Nucleotide sequence accession numbers. The GenBank accession numbers for the sequences of the case isolate are EF525554 (ITS), EF525555 (β-tubulin), and EF525556 (calmodulin).
