Running title: Novel canine astrovirus

Key words: astrovirus, dog, enteritis, small round viruses
Abstract

Infection by a novel canine astrovirus was associated with gastroenteritis in two dogs. The virus displayed 70.3-73.9% aa identity to other canine astroviruses in the full-length capsid. Specific antibodies were detected in the convalescent sera of the dogs, indicating seroconversion. Also, the virus appeared weakly related antigenically to the prototype canine astrovirus isolate ITA/2008/Bari.

Text

Astroviruses (AstVs) (Family Astroviridae) are small-rounded viruses (SRVs) with a peculiar star-like shape when observed by electron microscopy (EM), although this conformation is not always readily recognizable. AstV genome is composed of a plus-sense single-stranded RNA of 6.4-7.3 kb in size, containing 3 ORFs and with a 3' poly-A tail (13). Two ORFs, located at the 5' end of the genome (ORF1a and ORF1b), encode non-structural proteins, while ORF2, located at the 3' end, encodes the capsid protein (13). AstV infection is associated with gastro-enteritis in most animal species and human AstVs are regarded as the second or third most common cause of viral diarrhoea in children (13). AstVs have also been associated with extra-intestinal diseases, such as nephritis in chicken (10), hepatitis in ducks (16) and shaking syndrome in minks (1).

AstV-like particles have been detected only occasionally in dogs by EM either alone or in co-infection with other enteric viruses (11, 19, 21). More recently, AstVs have been identified in dogs with enteric signs and characterized molecularly, suggesting that the detected viruses may represent a distinct AstV species (12, 17, 22). Also, a canine AstV, strain ITA/08/Bari, was successfully adapted to replicate in vitro and AstV-specific antibodies were detected in canine sera (12).
Herewith we report an outbreak of AstV infection affecting two household dogs housed together, in Bari, Italy, 2010. One of the dogs (dog A), a 2-year-old mixed breed animal, developed anorexia and diarrhea, while the other animal (dog B), a 60-day-old mixed breed pup, was overtly healthy. The owner of the animals was requested to separate the animals and adopt preventive measures to avoid exposure of the pup (dog B) to potential infectious agents. Stools and sera of the two dogs were collected and subjected to virological and serological investigations. The samples tested negative for canine parvovirus (CPV-2), enteric coronaviruses (CCoVs), rotavirus, norovirus, adenovirus (CAV) and canine distemper (CDV) (4, 5, 6, 7, 9, 18). Dog A had been subjected to regular vaccination for major canine pathogens (CPV-2, CDV, CAV, Leptospira), while the pup (dog B) had started the immunization schedule with a modified live CPV-2 vaccine at 45 days of age. The faeces of dog A tested positive for astrovirus using primer pairs panAstVFor1 (GARTTYGATTGGRCKCGTAYGA), panAstVFor2 (GARTTYGATTGGRCKAGGTAYGA) and panAstVRev (GGYTTKACCCACATNCCRAA) (2). These primers target conserved nucleotide (nt) stretches in the RdRp region (ORF1b) and amplifies a 420-bp fragment (2). The stools of both the animals were collected daily and the animals were examined clinically, scoring the clinical signs as described elsewhere (3), but not including the white blood cells count. Bacterial and parasite pathogens were not identified in the stools of both the animals. On day 2 of quarantining (daq 2) dog A recovered completely from the disease. Despite the prophylaxis measures adopted, on daq 4 dog B developed acute severe gastro-enteritis with fluid diarrhea and vomiting. Astrovirus infection in dog B was confirmed by RT-PCR and EM observation of the stools. Appropriate therapy (re-hydration, anti-emetic, antibiotic and probiotics) was immediately started in the pup, although clinical signs were observed until daq 8.
The 3' end of ORF1b, the full-length ORF2 and the 3' non-coding region (approximately 3.5 kb) of the virus from dog B (strain ITA/2010/Zoid) was amplified with a 3' RACE protocol, as previously described (20) cloned and sequenced (accession number JN193534). The virus from dog A was also sequenced from the 3' end of ORF1b to the poly-A tail and was found to be identical (100% nt) to the virus identified from dog B. In the full-length capsid protein (ORF2), the virus displayed 70.3-73.9% aa identity to other canine AstV strains, while aa identity to other mammalian AstVs ranged from 18.3 to 33.2% (Table 1 and Figure 1). According to a new taxonomy proposal for mammalian AstVs, based on analysis of the full-length capsid protein, recently submitted to the International Committee for Taxonomy of Viruses (http://talk.ictvonline.org/files/proposals/taxonomy_proposals_vertebrate1/m/vert01/2287.aspx), AstV strains within the same species display a p-distance lower than 0.312. Therefore, all the canine AstV strains, including ITA/2010/Zoid can be classified as a unique species, GI.E (Table 1). The sequences of the novel AstV were used to optimize a specific real time RT-PCR (qRT-PCR) (submitted), designing novel primers CaAstV-F2 (ATTACCACGATGTTGYTCTGTR), CaAstV-R2 (CATGATTGGTATGTTGAAAAYTG) and probe CaAstVPb2 (6FAM-ATATGTACTTTTGCCATCAGGAG-BHQ1). The stools of dogs A and B were re-tested by the qRT-PCR in order to quantify the virus load. In dog A, AstV RNA was detected from daq -1 to 12, with the highest virus loads being detected between daq -1 and 1. Dog B shed AstV RNA from daq 3 to 36, when the quarantine and the study were ended, with the highest virus loads from daq 4 to 10 (Figure 2). By immunofluorescence using the canine isolate AstV ITA/2008/Bari as antigen (12), antibodies specific for canine AstV were not detected in the two dogs neither at daq 0, nor at daq 14 and daq 28. In immune electron microscopy, antibodies aggregating AstV particles were observed in convalescent (daq 28) but not in acute sera (daq 0).
indicating seroconversion. Also, weak antigenic cross-reactivity was observed between strain ITA/2008/Bari and ITA/2010/Zoid virus particles and sera in IEM. This could be accounted for by the genetic heterogeneity observed between the virus ITA/2010/Zoid and the prototype canine AstV isolate ITA/2008/Bari used as antigen. Attempts to adapt the virus ITA/2010/Zoid to growth in vitro on primary canine cells and on canine cell lines (MDCK and A72) were not successful thus hampering a precise evaluation of the antigenic relationships between the canine AstVs.

The findings of this study indicate that a unique canine AstV infected two dogs in a short time span. It is not clear whether dog B was already infected at daq 0 or it got infected after quarantining and which was the source of infection for the two animals.

It is also of relevance that we could correlate peaks of AstV shedding with the clinical signs, at least in pup B, which was followed almost entirely during the course of infection. Gastro-enteric signs (daq 4 to 8) in the pup were associated with the highest viral loads in the faeces ($10^7$ - $10^8$ copies of genome equivalents/gr of faeces). Such severe clinical picture could be easily attributed to other canine pathogens (CPV-2 or CCoV) by veterinarians. Surveys in Italy and China have revealed differences in AstV distribution between symptomatic (12.0-24.5%) and asymptomatic (0-9.3%) animals (12)(22). Overall, these findings suggest that AstVs may play a role as enteric pathogens of dogs.

Finally, there is evidence that canine AstVs are genetically and antigenically heterogeneous, with ranges of variation similar to those defined for human GLA AstV types 1-8 (14). Whether some strains can also vary in their patho-biological features is
not clear. For instance, some mink AstVs are able to invade and replicate in the central nervous system, causing disease, while others are not (1). Including canine AstVs in the algorithms of gastro-enteric diseases of dogs will be pivotal in order to portray a more complete picture of these viruses.

This work was funded by a grant from the Italian Ministry of Health, Ricerca corrente 2009, project IZS VE 21/09 RC “Definizione di una procedura validata per la selezione di cani per programmi di Interventi Assistiti dagli Animali (IAA)”
Table 1: comparison in the full-length capsid protein (ORF2) of the strain GLE/Zoid/ITA/2010 with other canine strains. The aa identity was calculated using a selection of sequences of 68 mammalian AstVs, without removing the gaps and with no distance correction, using the software Bioedit version 7.0.9.0 (8). The p-distance was calculated using the same sequence alignment, with MEGA package vers. 4.0 (15).

Figure legends

**Figure 1:** phylogenetic tree displaying the relationships among mammalian AstVs. The tree was calculated on the full-length aa capsid alignment without removing the gaps, using the neighbour-joining method with the p-distance correction, with 1000-replicates bootstrapping using the MEGA package vers. 4.0 (15). Bootstrap values lower than 75% are not shown. The canine AstV strain ITA/2010/Zoid is indicated with a solid circle. AstV species with assigned designation are indicated with the letter G followed by the romanic number and a capital letter. Strains with no assigned designation are indicated with a G. Abbreviations: ca, canine; fe, feline; hu, human; po, porcine; bo, bovine.

**Figure 2:** virus shedding and clinical scores in the two animals (dog A and dog B). Virus load is expressed as the logarithmic (log) value of the RNA copies/gr of feces. The clinical scores were calculated following the outlines of Decaro et al. (3), with minor modifications.
